1. a) Prove that the initial heapifying takes $O(n)$ operations.

- the height of the heap is $\lceil \log_2 n \rceil$
- at most $(\frac{n}{2})$ non-leaf nodes in the heap
- each level ' k ' of the heap has $(\frac{n}{2^{k+1}})$ nodes
- ↳ each node at level ' k ' has height ' k '

$$\sum_{h=0}^{\lceil \log_2 n \rceil} (\text{num nodes at lvl } h) \cdot O(h)$$

↓ substitute

$$\sum_{h=0}^{\lceil \log_2 n \rceil} \left(\frac{n}{2^{h+1}}\right) \cdot O(h)$$

$$O\left(n \sum_{h=0}^{\lceil \log_2 n \rceil} \frac{h}{2^h}\right) \rightarrow \sum_{h=0}^{\infty} \frac{h}{2^h} = 1 \quad O(n)$$

b) Define Average Case Complexity. Define an expression for the average case complexity of Quick sort over all possible inputs of a given size

Derivation:

- $T(n)$ = average-case running time of quick sort
- ↳ depends on how to partition which = $O(n)$
- ↳ depends on how to recursively sort the two arrays

Items to the left of pivot
Items to the right of pivot

when pivot is chosen randomly creating sub arrays $(i-1) \div (n-i)$ where i is the pivot index

Quicksort recursively sorts the two subarrays with times $T(i-1) \div T(n-i)$ Since pivot is chosen randomly, each pivot i has a $\frac{1}{n}$ probability of being selectedCombining everything: pivot i with $\frac{1}{n}$ probability of being selectedT(n) = $\frac{1}{n} \sum_{i=1}^n (T(i-1) + T(n-i)) + O(n)$ The average-case running time $T(n)$ is the weighted average of the times for all possible choices of the pivot $T(i-1) \div T(n-i)$ are symmetric becausewhen $i = \frac{n}{2}$: $T(\frac{n}{2}-1) = T(\frac{n}{2}) = T(\frac{n}{2}+1) = T(\frac{n}{2}+2) \rightarrow$ we can now $\sum_{i=1}^n T(n-i) = \sum_{i=1}^n T(i)$

we can rewrite as:

$$T(n) = \frac{1}{n} \sum_{i=1}^n T(i-1) + O(n) \quad \text{solve with summation} \quad T(n) = O(n \log n)$$

2. Solve the following recurrence using substitution method:

a) $T(n) = 3T(\frac{n}{4}) + n, T(1) = 1, n = 2^k$

sub $T(\frac{n}{4}) \cdot T(n) = 3(T(\frac{n}{4}) + n) = 3^2 T(\frac{n}{16}) + 3^2 \cdot n = 3^3 T(\frac{n}{64}) + 3^3 \cdot n = \dots$

Generalise substitution pattern: $T(n) = 3^k T(\frac{n}{2^k}) + n (1 \cdot 3^k \cdot \frac{3^k}{2^k} + \dots + \frac{3^{k-1}}{2^{k-1}})$

Combine terms:

$T(n) = n^{3^k} + n(1 \cdot 3^k \cdot \frac{3^k}{2^k} - 1) = n^{3^k} + 2n \cdot \frac{3^{2k-1}}{2^k} - 2n \leq n^{3^k} + 2n \cdot \frac{3^{2k-1}}{2^k} - 2n$

↳ $T(n) = 3n^{3^k} - 2n$ Dominant term: $O(n^{3^k})$

b) $T(n) = 2T(\frac{n}{2}) + n^2, T(1) = 1, n = 2^k$

sub $T(\frac{n}{2}) \cdot T(n) = 2(T(\frac{n}{2}) \cdot (\frac{n}{2})) + n^2 = 2^2 T(\frac{n}{4}) + 2^2 \cdot n^2$

sub $T(\frac{n}{4}) \cdot T(n) = 2^2 T(\frac{n}{4}) + 2^2 \cdot (\frac{n}{4})^2 + 2^2 \cdot n^2 = 2^3 T(\frac{n}{8}) + 2^3 \cdot (\frac{n}{8})^2 + 2^3 \cdot n^2$

Combine: $T(n) = n \cdot n^2 \cdot 2 \cdot (1 \cdot \frac{1}{2}) \Rightarrow T(n) = n \cdot 2 \cdot n \cdot n \Rightarrow T(n) = O(n^3)$

3. Compute the optimal cost and optimal parenthesis for multiplying the following matrices:

$A_1 | 15 \times 5, A_2 | 5 \times 10, A_3 | 10 \times 20, A_4 | 20 \times 25, A_5 | 25 \times 10$

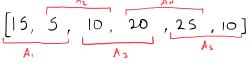

2 groupings

$A_1 A_2 = 15 \cdot 5 \cdot 10 = 750$
